

PHYTOSEIID MITES OF THE CANARY ISLANDS (ACARI, PHYTOSEIIDAE). II. TENERIFE AND LA GOMERA ISLANDS

F. Ferragut* & M. A. Peña-Estévez**

ABSTRACT

Phytoseiid mites (Acari, Phytoseiidae) inhabiting plants in natural ecosystems from Tenerife and La Gomera islands (Canary Islands) have been studied. Surveys were conducted from 1997 to 2002. Eleven species were collected, one of them being reported for the first time from the Canary Islands and six of them reported for the first time from Tenerife and La Gomera islands. *Euseius machadoi n. sp.* collected from woody plants in the Canarian laurisilva is proposed as a new species.

Key words: Acari, Phytoseiidae, *Euseius machadoi*, Tenerife, La Gomera, Canary Islands.

RESUMEN

Ácaros Fitoseídos de las islas Canarias (Acari, Phytoseiidae). II. Tenerife y La Gomera

En muestreos realizados desde 1997 hasta 2002 se ha estudiado la fauna de ácaros fitoseídos (Acari, Phytoseiidae) asociada a plantas de ecosistemas naturales de las islas de Tenerife y La Gomera (Islas Canarias). Se han recolectado un total de 11 especies, siendo una de ellas citada por vez primera en las islas Canarias y seis de ellas citadas por primera vez en las islas de Tenerife y La Gomera. *Euseius machadoi n. sp.*, recolectado en plantas leñosas de la laurisilva canaria, se propone como una nueva especie.

Palabras clave: Acari, Phytoseiidae, *Euseius machadoi*, Tenerife, La Gomera, Islas Canarias.

Introduction

The mite family Phytoseiidae includes about 2300 species, which are found in all parts of the world except the Polar Regions (Moraes *et al.*, 2004). They are the most common group of predatory mites inhabiting higher plants, and the incre-

se in our knowledge during the last 40 years has been due to their importance as biological control agents of pests on many crops (Helle & Sabelis, 1985; Gerson *et al.*, 2003).

Due to their agricultural importance, the species found in agricultural zones of Europe and North America are relatively well known, but little is

known of those that occur in many natural ecosystems. However, our knowledge of phytoseiid species that live in natural or little altered (non-agricultural) ecosystems in the Canary Islands has grown substantially in recent years (Ferragut & Peña-Estévez, 2003; Moraza *et al.*, 2005; Moraza & Peña-Estévez, 2005a, 2005b, 2006). Thus, 27 species are now known from such habitats, nine of them being endemic to the islands.

This study may be considered the second part of a previous publication (Ferragut & Peña-Estévez, 2003) in which the phytoseiid species of Gran Canaria were studied and it is intended to increase our knowledge of this group of plant mites in Tenerife and La Gomera, presenting data on the species found, their relative importance, geographical distribution, habitat preference and host plants.

Materials and Methods

Several surveys were conducted from November 1997 to December 2002 on plants from natural non-agricultural ecosystems from Tenerife and La Gomera. A total of 145 samples were collected from Tenerife and 107 from La Gomera island. A list of localities, habitats and georeferencing data can be found in Appendix 1. Phytoseiid mites were collected using a mite brushing machine and Berlese funnels. The mites were cleared in Nesbitt fluid and mounted on Heinze-PVA medium. Observations were made using an interference contrast microscope. All measurements in this paper are given in micrometers (μm). Setal nomenclature follows that of Rowell *et al.* (1978), and the nomenclature used for the dorsal solenostomes or gland openings (gd1-gd9) is that proposed by Athias-Henriot (Athias-Henriot, 1975; Swirski *et al.*, 1998). Generic nomenclature follows the criteria recently proposed by Chant & McMurtry (2007). All the specimens were collected by M. A. Peña-Estévez. The holotype and paratypes of the new species are deposited in the Museo Nacional de Ciencias Naturales in Madrid (MNCN). Other type material can be found in the collection belonging to the Instituto Agroforestal Mediterráneo, Universidad Politécnica de Valencia.

Results

SPECIES COLLECTED

A total of 305 specimens were collected, 196 in Tenerife and 109 in La Gomera. The material was grouped into 11 species, seven from Tenerife and

eight from La Gomera. The paper also includes the description of a new species of the genus *Euseius* Wainstein, 1962.

Family Phytoseiidae Berlese, 1916

Subfamily Amblyseiinae Muma, 1961

Amblyseius herbicolus (Chant, 1959)

Typhlodromus (Amblyseius) herbicolus. The Canadian Entomologist, 12: 84.

SPECIMENS EXAMINED – **Tenerife:** Eleven females on *Viburnum rigidum* (Caprifoliaceae) and 3 females on *Woodwardia radicans* (Blechnaceae), Hoya de Ijuana, 15 November 1997; 4 females on *Laurus novocanariensis* (Lauraceae), Pedro Alvarez, 29 November 1997; 8 females on *Rubus ulmifolius* (Rosaceae) and 16 females on *Laurus novocanariensis* (Lauraceae), El Moquinal, 29 November 1997; 5 females on *Hedera helix* (Araliaceae), Llano de los Viejos, 29 November 1997. **La Gomera:** One female on *Laurus novocanariensis* (Lauraceae), Bco. El Cedro, 30 May 2002; one female and one male on *Rhamnus glandulosa* (Rhamnaceae), Bosque de los Mástiles, 7 December 2002.

REMARKS – Species of a wide geographical distribution, including tropical and subtropical areas around the world. Previously reported from Gran Canaria by Ferragut & Peña-Estévez (2003).

Euseius machadoi new species

TYPE MATERIAL. Holotype and paratypes deposited in MNCN (holotype catalog nº 20.02/17046; paratypes nº 20.02/17047 and nº 20.02/17048). **Tenerife:** Holotype female, 3 paratype females and 3 males on *Myrica faya* (Myricaceae), Las Rosas, 25 May 1999; 5 paratype females and 2 males on *Laurus novocanariensis* (Lauraceae), Pedro Alvarez, 29 November 1997.

La Gomera: One paratype male on *Ilex canariensis* (Araliaceae) and 1 paratype male on *Hedera canariensis* (Araliaceae), Chorros de Epina, 1 June 2002. **Gran Canaria:** One paratype female on *Laurus novocanariensis*, Zumacal, 14 December 1998.

DIAGNOSIS. Dorsal shield about 400 long. Dorsal surface smooth with a few anterolateral and posterior striae. Irregular lateral margins. Seventeen pairs of short, thick, pointed and smooth dorsal setae, except Z5 which is slightly serrated; the longest being j1, j3, s4 and Z5. Seven pairs of dorsal solenostomes: gd1, gd2, gd4, gd5, gd6, gd8 and gd9. Peritreme very short, reaching to level of z4. In the insemination apparatus the calix is long, cone-shaped and flaring distally. Ventrianal shield wider at the level of setae ZV2 than at level of anal opening. Four thick, sharp macrosetae on genu III, genu IV, tibia IV and tarsus IV.

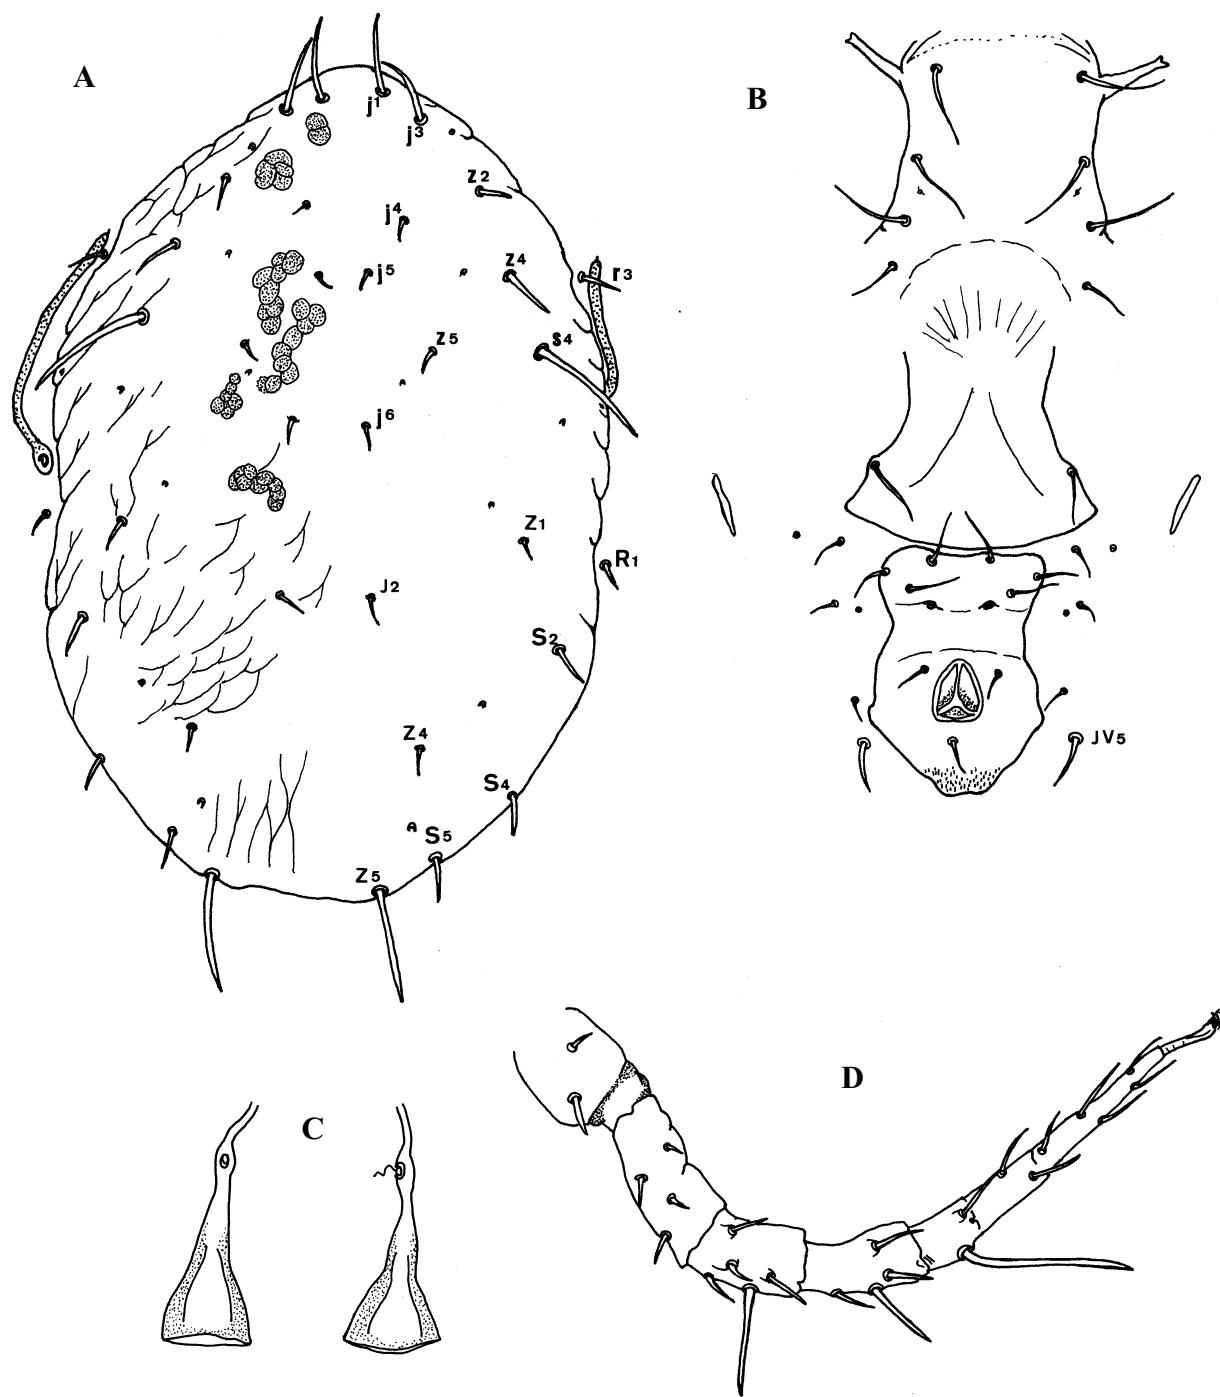

Fig. 1.—*Euseius machadoi* n. sp., female. A) dorsal shield, B) ventral surface, C) insemination apparatus, D) macrosetae on leg IV.

Fig. 1.—*Euseius machadoi* n. sp., hembra. A) escudo dorsal, B) superficie ventral, C) aparato inseminador, D) macroseta de la pata IV.

FEMALE (Fig. 1) (Dimensions of the holotype with the variations in the measurements of the paratypes in parentheses. Seven females measured).

Dorsum (Fig. 1A) – Oval-shaped dorsal shield, 404 long (354-410) and 270 wide (208-278). Dorsal surface smooth with a few lateral striae, faintly reticulated or striated posteriorly, especially in the region between Z1 and Z4. Irregular lateral margins, with indentations between j3 and S2. Seventeen pairs of thick, pointed and smooth setae, except Z5 which is slightly serrated. All setae short or very short, with j1, j3, s4 and Z5 being the longest. Setae j1: 40 (34-42); j3: 32 (28-32); j4, j5 and j6: 8 (7-9); J2: 10 (8-10); J5: 8 (8-9); z2: 12 (11-13); z4: 24 (20-24); z5: 8 (7-9); Z1: 14 (12-15); Z4: 14 (11-14); Z5: 50 (46-52); s4: 58 (52-60); S2 and S4: 18 (16-18); S5: 20 (16-22); r3 and R1: 16 (14-17). Seven pairs of dorsal solenostomes: gd1, gd2 and gd5 small and punctiform; gd4, gd6 and gd8 punctiform and gd9 crescentic. Gland gd8 well separated and exterior to Z4, gland gd9 interior to S5. Peritreme very short, reaching to level of z4. Peritremal shield terminating in sublateral integument.

Venter (Fig. 1B) – Smooth, quadrangular sternal shield, with three pairs of setae (ST1, ST2 and ST3). Posterior margin weakly sclerotized and difficult to discern. Setae ST4 apparently on the soft integument. Genital shield wider than ventrianal. Ventrianal shield vase-shaped, with smooth surface, 118 (104-120) long, slightly wider at level of seta ZV2, 78 (70-80), than at level of anal opening, 72 (66-72). With three pairs of preanal setae aligned in two transverse rows on the anterior third of the shield and a pair of crescentic preanal solenostomes. Four pairs of setae around the ventrianal shield, JV5 being pointed and thick, 20 (18-20). Primary metapodal plate 30 (26-33) long.

Spermatheca (Fig. 1C) – Calix long, cone-shaped, 32 (28-34), flaring distally, with walls and slightly bulging at the level of atrium.

Chelicerae – Short cheliceral digits; fixed digit with three small teeth, movable digit with one tooth.

Legs – Measurements of legs as follows: pI: 410; pII: 340; pIII: 376; p IV: 464. Macrosetae thick and sharp, present on genu III: 32 (26-32), genu IV: 62 (45-65), tibia IV: 40 (32-42) and tarsus IV: 92 (72-92) (Fig. 1D).

MALE (Fig. 2) (Four specimens measured).

Dorsum (Fig. 2A) – Oval dorsal shield, 310 long, 222 wide, with faintly marked striae on the lateral

margins and irregular margins, especially in the opistonothal region. Seven pairs of solenostomes, gd1, gd2, gd4, gd5, gd6, gd8 and gd9. Nineteen pairs of smooth, thick and pointed dorsal setae. Setae r3 and R1 on dorsal shield; j1: 32 (28-33); j3: 32 (30-34); j4 and j5: 6 (5-6); j6: 9 (9-10); J2: 10 (10-11); J5: 6 (6); z2: 16 (15-18); z4: 25 (23-28); z5: 6 (6); Z1: 15 (14-16); Z4: 14 (13-16); Z5: 45 (43-47); s4: 42 (40-44); S2 and S4: 20 (18-22); S5: 22 (20-26); r3 15 (14-16) and R1: 11 (11-12). Peritreme reaching the level of z4 or between z2-z4.

Venter – Triangular ventrianal shield 126 long (124-128) and 196 wide (189-204), fused with peritrematal shields (Fig. 2B), with striated surface, three pairs of preanal setae and preanal pores.

Chelicerae (Fig. 2C) – Fixed digit with 3 or 4 teeth distal to *pilus dentilis*, movable digit with 1 tooth.

Spermatodactyl (Fig. 2C) – L-shaped with a long foot, two apical lobes and a small pointed process. The outer margin of the shaft carries a membranous border.

Legs – Macrosetae on genu III not discernible; thick and sharp macrosetae on genu IV 36 (34-38), tibia IV 28 (28-30) and tarsus IV 72 (64-75).

ETYMOLOGY: This species is dedicated to the coleopterologist Antonio Machado for his contribution to the knowledge of the arthropod fauna and the conservation of natural habitats in the Canary Islands.

REMARKS: *E. machadoi* is very similar morphologically to *E. spermahyphus* (Ueckermann & Loots) described from South Africa on *Senecio pterophorus* (Ueckermann & Loots, 1988). It differs from *E. spermahyphus* in the shape of the calyx in the spermatheca, long and cone-shaped in *E. machadoi* and long and filamentous in *E. spermahyphus*; the length of the peritremes, reaching setae z4 in *E. machadoi* and the level between z2-z4 in *E. spermahyphus*; the number of teeth on the fixed digit of the chelicera, three small teeth in *E. machadoi* instead of 7 teeth in *E. spermahyphus*; and finally in the length of dorsal setae, which are shorter in *E. spermahyphus*.

***Euseius scutalis* (Athias-Henriot, 1958)**

Typhlodromus scutalis. Revue de Pathologie Vegetale et d'Entomologie Agricole, 37(2): 183

SPECIMENS EXAMINED – Tenerife: One female on *Asparagus pastorianus* (Liliaceae), Barranco del Infierno, 23 November 1997.

Seius degenerans. Tipografia del Seminario, 6(54): 9

SPECIMENS EXAMINED — **La Gomera:** One female on *Mentha* sp. (Lamiaceae), Hornillo, 31 May 2002.

REMARKS — Species of tropical and subtropical distribution. Very common in all the Canary Islands on weeds and some crops. Reported from Tenerife Island by Pande *et al.*, (1989).

Kampimodromus hmiminai McMurtry & Bounfour, 1989
Acarologia, 30(1): 17

SPECIMENS EXAMINED — **La Gomera:** Ten females and 2 males on *Salix canariensis* (Salicaceae), Hornillo, 31 May 2002.

REMARKS — Described from northern Morocco by McMurtry & Bounfour (1989), it is found in the Western Mediterranean, being collected in France (Tixier *et al.*, 2006) and Spain (unpublished data). This is the first record of this species from the Canary Islands. Recent genetic studies (Tixier *et al.*, 2006) show that it is conspecific with *K. adrianae* described by Ferragut & Peña-Estevez (2003) in Gran Canaria island (see comments in Discussion).

SPECIMENS EXAMINED – **Tenerife:** One female on *Convolvulus* sp. (Convolvulaceae), Barranco del Inferno, 23 November 1997; 1 male on *Argyranthemum frutescens* (Asteraceae), Bajamar, 29 November 1997; 1 female on *Lavandula buchii* (Lamiaceae), Barranco del Tomadero, 29 November 1997; 7 females, 2 males and 1 immature on *Viburnum rigidum* (Caprifoliaceae), Llano de los Viejos, 26 May 1999; 2 females and 1 immature on *Senecio tussilaginis* (Asteraceae) and 4 females and 1 male on *Calamintha sylvatica* (Lamiaceae), El Tanque, 27 May, 1999; 1 female on *Geranium canariensis* (Geraniaceae), 5 females and 3 males on *Senecio tussilaginis* (Asteraceae), 2 males on *Crambe strigosa* (Cruciferae), 1 female on *Cedronella canariensis* (Lamiaceae) and 8 females and 2 males on *Viburnum rigidum* (Caprifoliaceae), Monte del Agua, 27 May 1999; 1 male on *Argyranthemum gracile* (Asteraceae), Palm Mar, 18 April 2000. **La Gomera:** One female on *Viburnum rigidum* (Caprifoliaceae) and 1 male on *Cedronella canariensis* (Lamiaceae), Apartacaminos, 30 May 2002; 1 female on *Laurus novocanariensis* (Lauraceae), 3 females and 2 males on *Gesnouinia arborea* (Urticaceae), 1 male on *Scrophularia smithii* (Scrophulariaceae) and 1 male on *Viola riviniana* (Violaceae), Barranco El Cedro, 30 May 2002; 4 males on *Echium acanthocarpum* (Boraginaceae) and 1 male on *Teline gomerae* (Leguminosae), Meriga, 30 May 2002; 2 females and 2 males on *Erica scoparia* (Ericaceae), Mirador El Bailadero, 6 December 2002; 3 females, 1 male and 2 immatures on *Gonospermum gomerae* (Asteraceae), Las Rosas, 7 December 2002; 1 female and 1 male on *Andryala pinnatifida* (Asteraceae), Teselinde, 7 December 2002.

REMARKS – Species described from Gran Canaria (Ferragut & Peña-Estévez, 2003). Apparently, the distribution range includes other islands in the Canaries.

RELATIVE ABUNDANCE OF PHYTOSEIID MITE SPECIES

Table 1 show the species captured on each island, their abundance, relative importance and frequency of appearance in the total samples. The results show that *Typhlodromus (Anthoseius) rhenanoides* and *Neoseiulella canariensis* are the most abundant species in the prospected zones of the two islands, with *Amblyseius herbicolus* and *Typhlodromus (Anthoseius) maspalomensis* also being abundant species in Tenerife and La Gomera, respectively. The relative importance of these species is confirmed because they constitute more than 90% of the phytoseiid collected in Tenerife and 85% in La Gomera. The rest of the species are scarce or are associated with one of the plants collected.

Typhlodromus rhenanoides is also the most frequent species, since it appears in 18% of the Tenerife samples and 12% of those from La Gomera. *Neoseiulella canariensis* is the second most frequent, appearing in more than 8% of sam-

ples from Tenerife and 11.2% from La Gomera. The frequency of appearance of the other species, even *A. herbicolus* and *T. maspalomensis*, is low, since they were found in few samples, although their abundance was quite high.

Discussion

This study reports the presence of 11 phytoseiid species in little altered habitats of Tenerife and La Gomera islands. Only one, *Kampimodromus hmiminae*, had not previously been reported for the Canary Islands (see commentary on this species) and another, *Euseius machadoi*, is proposed as a new taxon for science. This means that the results obtained were relatively poor despite the effort put into sampling and the period during which the samples were collected. The paucity is even more notable if we compare the results obtained in Gran Canaria with a similar sampling effort, when 21 species of phytoseiids were captured, six of them new species (Ferragut & Peña-Estévez, 2003) and take into account that the ecosystems sampled, which included the laurisilva and the National Parks Las Cañadas del Teide and Garajonay, are known to be rich in species of other arthropods. Perhaps other reasons such as differences between sampling periods or the plant diversity of ecosystems could better explain these results.

The relative importance of the different species is similar to that found in Gran Canaria, where *T. rhenanoides* and *N. canariensis* are the most common species on plants in non-altered environments.

The new taxon described, *Euseius machadoi*, was found on both islands, and on Gran Canaria, which means it is widespread distributed, although it is not abundant. It also seems to be associated with woody plants typical of the Canarian *monte-verde*, such as *Laurus novocanariensis*, *Myrica faya* and *Ilex canariensis*, characterised by large smooth leaves with no hairs or trichomes.

On La Gomera, we collected *K. hmiminae*, a species considered until recently as very close to *Kampimodromus adrianae* Ferragut & Peña-Estévez, 2003 described from Gran Canaria. In a recent morphological and genetic study of both species, using specimens of *K. adrianae* from Gran Canaria and *K. hmiminae* from France and Morocco, Tixier *et al.*, (2006) found that, although morphologically similar, the species can be easily distinguished by the length of their dorsal setae. However, a comparison of mitochondrial DNA fragments showed that the differences

Table 1.— Abundance of phytoseiid species collected in Tenerife and La Gomera Islands. Abundance is the total number of mites, relative abundance is the percentage of each species compared with the total number of phytoseiids and frequency is the frequency of occurrence of each species on the total samples taken in Tenerife and La Gomera.

Tabla 1.— Abundancia de las especies de fitoseidos recolectadas en las islas de Tenerife y La Gomera. Abundancia es el número total de ejemplares de cada especie, abundancia relativa el porcentaje de cada especie en relación al número total de fitoseidos y frecuencia la frecuencia de aparición de cada especie en el total de muestras tomadas en Tenerife y La Gomera.

<i>Iphiseius degenerans</i>	1	0.9%	0.9%
Total	109		

are less than might be expected in different species, so that any morphological differences may be due to intraspecific variability. The variation in dorsal seta length, one of the most widely used characters in the taxonomy of phytoseiids for separating species, had already been discussed in the case of *Kampimodromus aberrans* (Oudemans, 1930) by Chant (1955) and Ragusa & Tsolakis (1994). These authors observed that two forms of the species existed, one of which appeared in summer with long, serrated dorsal setae and the other in winter with shorter, thinner and less serrated dorsal setae. However, the appearance of larger setae in summer does not seem to be a characteristic of *K. adrianae*/*K. hmiminai*, since most of the specimens of *K. adrianae* (lar-

ger and thicker setae) were collected in the Canary Islands in November (some in August), while *K. hmiminai* (smaller, thinner setae) was collected in May. Curiously, both species, or morphospecies, were always found associated with the same host plant, the endemic Salicaceae *Salix canariensis*.

ACKNOWLEDGEMENTS

The authors wish to thank the authorities from the Cabildos of Tenerife and La Gomera islands, and the National Parks of Cañadas del Teide and Garajonay for providing the permits to collect the samples.
